

# Universal Decade Counter

The MC10137 is a high speed synchronous counter that can count up, down, preset, or stop count at frequencies exceeding 100 MHz. The flexibility of this device allows the designer to use one basic counter for most applications. The synchronous count feature makes the MC10137 suitable for either computers or instrumentation.

Three control lines (S1, S2, and Carry In) determine the operation mode of the counter. Lines S1 and S2 determine one of four operations; preset (program), increment (count up), decrement (count down), or hold (stop count). Note that in the preset mode a clock pulse is necessary to load the counter, and the information present on the data inputs (D0, D1, D2, and D3) will be entered into the counter. Carry Out goes low on the terminal count. The Carry Out on the MC10137 is partially decoded from Q1 and Q2 directly, so in the preset mode the condition of the Carry Out after the Clock's positive excursion will depend on the condition of Q1 and/or Q2. The counter changes state only on the positive going edge of the clock. Any other input may change at any time except during the positive transition of the clock. The sequence for counting out of improper states is as shown in the State Diagrams.

## MC10137

1. Individually apply  $V_{ILmin}$  to pin under test.

2. Measure output after clock pulse   $V_{IH}$  appears at clock input (Pin 13).

3. Before test set Q1 and Q2 outputs to a logic low.

1. Individually test each input; apply V<sub>ILmin</sub> to pin under test.
2. Measure output after clock pulse  VIH appears at clock input (Pin 13).
3. Before test set all Q outputs to a logic high.

Each MECL 10,000 series circuit has been designed to meet the dc specifications shown in the test table, after thermal equilibrium has been established. The circuit is in a test socket or mounted on a printed circuit board and transverse air flow greater than 500 linear fpm is maintained. Outputs are terminated through a 50-ohm resistor to -2.0 volts. Test procedures are shown for only one gate. The other gates are tested in the same manner.

SWITCHING TIME TEST CIRCUIT AND WAVEFORMS @ 25°C

- (a) is the minimum time to wait after the counter has been enabled to clock it.
- (b) is the minimum time before the counter has been disabled that it may be clocked.
- (c) is the minimum time before the counter is enabled that a clock pulse may be applied with no effect on the state of the counter.
- (d) is the minimum time to wait after the counter is disabled that a clock pulse may be applied with no effect in the state of the counter.
- (b) and (c) may be negative numbers.

NOTE:

$t_{setup}$  is the minimum time before the positive transition of the clock pulse (C) that information must be present at the input D or S.

$t_{hold}$  is the minimum time after the positive transition of the clock pulse (C) that information must remain unchanged at the input D or S.

Input Pulse  
 $t_+ = t_- = 2.0 \pm 0.2$  ns  
 (20 to 80%)

50-ohm termination to ground located in each scope channel input. All input and output cables to the scope are equal lengths of 50-ohm coaxial cable. Wire length should be < 1/4 inch from TP<sub>in</sub> to input pin and TP<sub>out</sub> to output pin. Unused outputs are connected to a 50-ohm resistor to ground.
